1. Introduction

In this project, we use the Flask Framework to deploy the machine learning model Random Forest (RF) classifier. As an example, our approach helps to predict the species of flowers. Utilizing Flask, the Python micro-framework for developing web applications, establish an API for the model. Through HTTP queries, this API enables us to make use of predictive capabilities.

2. Data Information

Iris is a sample dataset that was acquired from Kaggle and stored as a CSV file. The independent and dependent variables of the dataset are listed in the table below. Class is the dependent variable, whereas Sepal Length, Sepal Width, Petal Length, and Petal Width are independent variables.

Id	Sepal_Length	Sepal_Width	Petal_Length	Petal_Width	Species
1	5.1	3.5	1.4	0.2	Iris-setosa
2	4.9	3	1.4	0.2	Iris-setosa
3	4.7	3.2	1.3	0.2	Iris-setosa
4	4.6	3.1	1.5	0.2	Iris-setosa
5	5	3.6	1.4	0.2	Iris-setosa

Table 2.1: Dataset Information

3. Building a Model

- Initially, We import the required libraries.

```
1 import pandas as pd
2 from sklearn.preprocessing import StandardScaler
3 from sklearn.ensemble import RandomForestClassifier
4 from sklearn.model_selection import train_test_split
5 import pickle
```

- Load the Dataset

```
8 #load the csv file
9
10 df = pd.read_csv("Iris.csv")
11
```

- Dataset Details

```

12 df.head()
13
14 #Dataset Details
15 print(df.head(5))
16 print(df.size)
17 print(df.shape)
18 print(df.keys())

```

	Id	Sepal_Length	Sepal_Width	Petal_Length	Petal_Width	Species
0	1	5.1	3.5	1.4	0.2	Iris-setosa
1	2	4.9	3.0	1.4	0.2	Iris-setosa
2	3	4.7	3.2	1.3	0.2	Iris-setosa
3	4	4.6	3.1	1.5	0.2	Iris-setosa
4	5	5.0	3.6	1.4	0.2	Iris-setosa

```

900
(150, 6)
Index(['Id', 'Sepal_Length', 'Sepal_Width', 'Petal_Length', 'Petal_Width',
      'Species'],
      dtype='object')

```

- Select Independent and dependent variable

```

22 #Select independent and dependent variable
23 x = df[["Sepal_Length", "Sepal_Width", "Petal_Length", "Petal_Width"]]
24 y = df["Species"]

```

3.1. Build Model

We use a machine learning model to classify the different types of flowers. We use scikit-learn to implement Random Forest (RF) for this purpose. Fit the Random Forest model onto the training dataset after importing and initialising it.

```

26 #Split the dataset into train and test
27 x_train, x_test, y_train, y_test = train_test_split(x, y, test_size=0.3, random_state=50)
28
29 #Feature scaling
30 sc = StandardScaler()
31 x_train = sc.fit_transform(x_train)
32 x_test = sc.transform(x_test)
33
34 #Instantiate the model
35 classifier = RandomForestClassifier()
36
37 #Fit the model
38 classifier.fit(x_train, y_train)

```

3.2. Save the model

After that, we use Pickle to save the model.

```

40 #Make pickle file of our model
41 pickle.dump(classifier, open("model.pkl", "wb"))

```

4. Turning Model into Flask Framework

We create a simple online page with fields for Sepal Length, Sepal Width, Petal Length, and Petal Width that allows us to enter the length as a web application. If we click "predict" after filling out the length, it will reveal the species type.

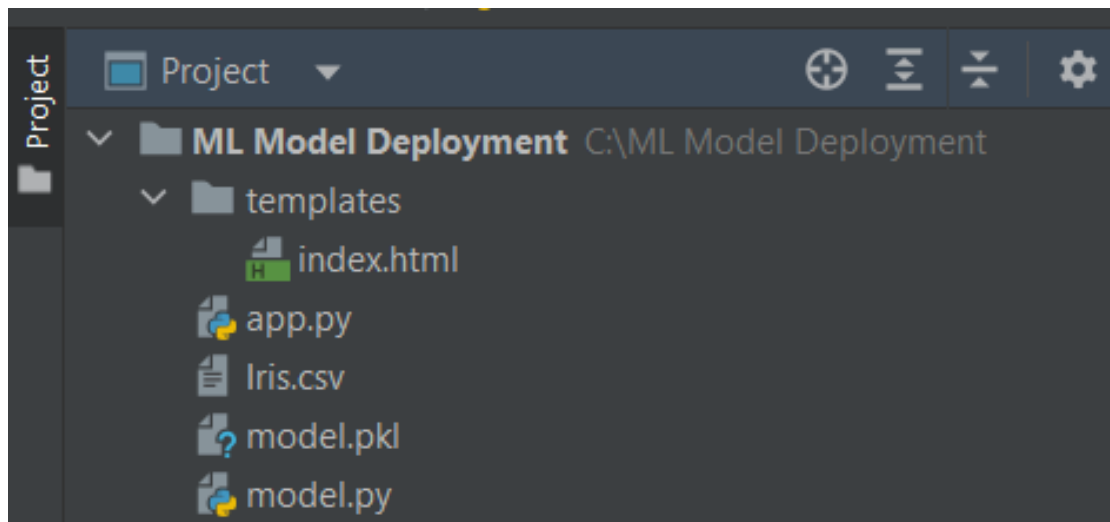

Table 4: Application Folder File Directory

For this project, we first create a folder called ML Model Deployment. The folder's file tree is represented by this. Each file's description is provided in the sections below. In our application, there is only one HTML file called index.html in the sub-directory templates, which is where Flask would seek static HTML files to render in the web browser.

4.1. App.py

The essential code for running the Flask web application, including the machine learning (ML) code for classification, is contained in the app.py file.

```

1 import numpy as np
2 from flask import Flask, request, jsonify, render_template
3 import pickle
4
5 #Create flask app
6 app = Flask(__name__)
7
8 #Load the pickle model
9 model = pickle.load(open("model.pkl", "rb"))
10
11 @app.route("/")
12 def Home():
13     return render_template("index.html")
14 @app.route("/predict", methods = ["post"])
15 def predict():
16     float_features = [float(x) for x in request.form.values()]
17     features = [np.array(float_features)]
18     prediction = model.predict(features)
19
20     return render_template("index.html", prediction_text = "The flower species is {}".format(prediction))
21
22 if __name__ == "__main__":
23     app.run(debug=True)
24

```

Figure 4.1: App.py

- In order to inform Flask that it may locate the HTML template folder (templates) in the same directory where it is located, we initialized a new Flask instance with the argument `__name__`. This is because we ran our application as a single module.
- The URL that should cause the home function to run was then specified using the route decorator (`@app.route('/')`).
- The form data was sent to the server in the message body using the POST method. We further activated Flask's debugger by setting the `debug=True` option inside the `app.run` method.
- Finally, we utilised the `run` function to only launch the server-side application when the Python interpreter performed this script directly, which we verified using the if statement with `__name__ == "__main__"`.

4.2. Index.html

The following are the contents of the `index.html` file that will render a text form where a user can enter the length of the flower.

```

1  <!DOCTYPE html>
2  <html>
3  <!-- From https://codepen.io/frytyler/pen/E6dtg-->
4  <head>
5    <meta charset="UTF-8">
6    <title>ML API</title>
7    <link href='https://fonts.googleapis.com/css?family=Pacifico' rel='stylesheet' type='text/css'>
8    <link href='https://fonts.googleapis.com/css?family=Arimo' rel='stylesheet' type='text/css'>
9    <link href='https://fonts.googleapis.com/css?family=Hind:300' rel='stylesheet' type='text/css'>
10   <link href='https://fonts.googleapis.com/css?family=Open+Sans+Condensed:300' rel='stylesheet' type='text/css'>
11 </head>
12 <body>
13   <div class="login">
14     <h1>Flower Class Prediction</h1>
15
16     <!-- Main Input For Receiving Query to our ML -->
17     <form action="{{ url_for('predict')}}" method="post">
18       <input type="text" name="Sepal_Length" placeholder="Sepal_Length" required="required" />
19       <input type="text" name="Sepal_Width" placeholder="Sepal_Width" required="required" />
20       <input type="text" name="Petal_Length" placeholder="Petal_Length" required="required" />
21       <input type="text" name="Petal_Width" placeholder="Petal_Width" required="required" />
22
23       <button type="submit" class="btn btn-primary btn-block btn-large">Predict</button>
24     </form>
25     <br>
26     <br>
27     {{ prediction_text }}
28   </div>
29 </body>
30 </html>

```

Figure 4.2: index.html

4.3. Running Procedure

Once we have completed everything above, we can launch the API by double clicking app.py or by using the following command in the terminal:

```

"C:\Users\BALAJI RAMYA\anaconda3\python.exe" "C:/ML Model Deployment/app.py"
* Serving Flask app "app" (lazy loading)
* Environment: production
  WARNING: This is a development server. Do not use it in a production deployment.
  Use a production WSGI server instead.
* Debug mode: on
* Restarting with watchdog (windowsapi)
* Debugger is active!
* Debugger PIN: 753-831-909
* Running on http://127.0.0.1:5000/ (Press CTRL+C to quit)

```

Figure 4.3: Command Execution

We could now launch a web browser and go to <http://127.0.0.1:5000/> to see a straightforward webpage with the content shown below.

Flower Class Prediction

Sepal_Length	Sepal_Width	Petal_Length	Petal_Width	Predict
--------------	-------------	--------------	-------------	---------

Figure 4.4: Flower Class Prediction Website Page

Now we enter the length in each field.

Flower Class Prediction

5.1	3.5	1.4	0.2	Predict
-----	-----	-----	-----	---------

Figure 4.5: Input in the form

Clicking the "predict" button after entering the inputs allows us to see the outcome of our input.

Flower Class Prediction

Sepal_Length	Sepal_Width	Petal_Length	Petal_Width	Predict
--------------	-------------	--------------	-------------	---------

The flower species is ['Iris-virginica']

Figure 4.6: Result of the given input

5. Model Deployment using Heroku

Now that our model has been trained, the machine learning pipeline has been set up, and the application has been through local testing, we are prepared to begin our Heroku deployment. The source code for the application can be uploaded to Heroku in a few different ways. Connecting a GitHub repository to your Heroku account is the simplest method.

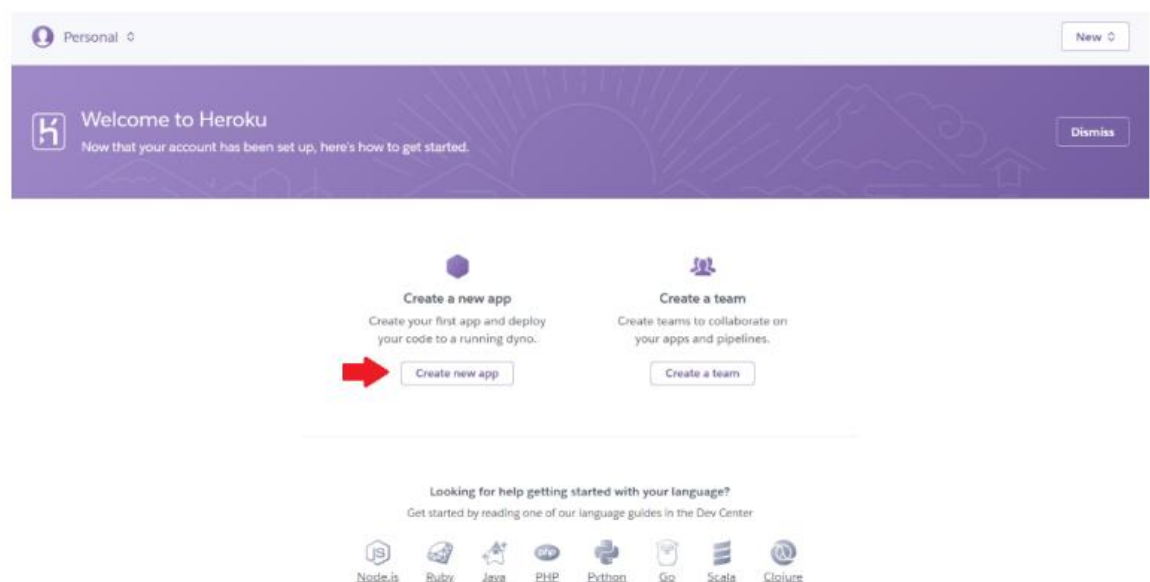

Requirement.txt

It is a text file that contains the necessary Python packages to run the application.

5.1. Steps for Model Deployment Using Heroku

We are now prepared to begin deployment on Heroku after uploading the necessary files to the GitHub repository. The steps are as follows:

- I. After registering on Heroku.com, select Create new app.

- II. Enter the App name and region

App Name

flowerpredictionapp

Region

 United States

III. Connect the GitHub repository where the code I uploaded is located.

Deployment method

Heroku Git
Use Heroku CLI

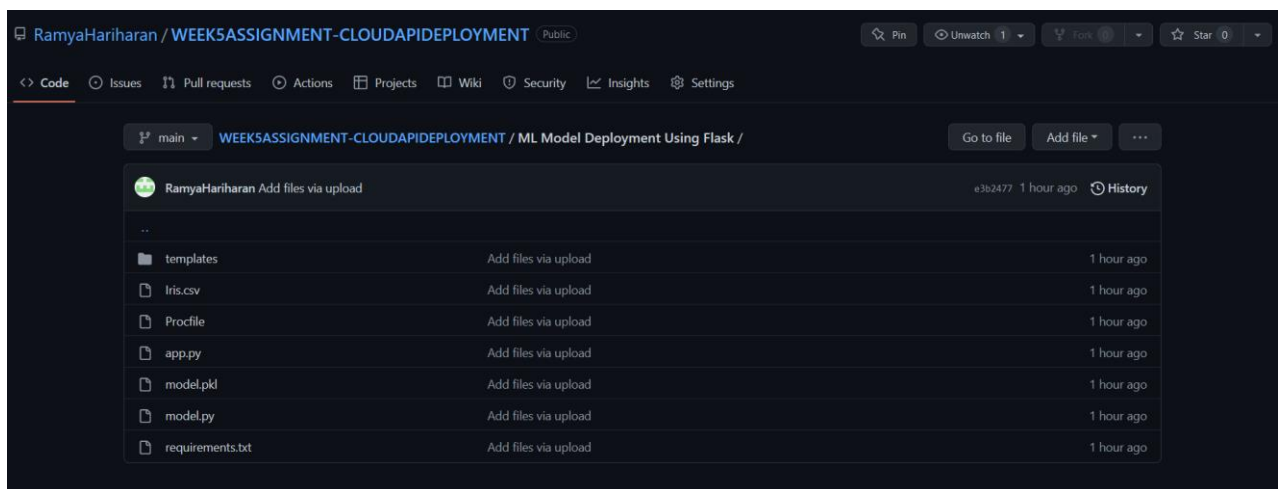

GitHub
Connected

Container Registry
Use Heroku CLI

I then select the repository and upload the code there.

IV. Deploy branch

Automatic deploys

Enables a chosen branch to be automatically deployed to this app.

Enable automatic deploys from GitHub

Every push to the branch you specify here will deploy a new version of this app. **Deploys happen automatically:** be sure that this branch is always in a deployable state and any tests have passed before you push. [Learn more.](#)

Choose a branch to deploy

master

☐ Wait for CI to pass before deploy

Only enable this option if you have a Continuous Integration service configured on your repo.

Enable Automatic Deploys

Manual deploy

Deploy the current state of a branch to this app.

Deploy a GitHub branch

This will deploy the current state of the branch you specify below. [Learn more.](#)

Choose a branch to deploy

master

Deploy Branch

V. Five to ten minutes later, our application is ready.

Manual deploy

Deploy the current state of a branch to this app.

Deploy a GitHub branch

This will deploy the current state of the branch you specify below. [Learn more.](#)

Choose a branch to deploy

master

Deploy Branch

Receive code from GitHub

Build master 3a3e6e70

Release phase

Deploy to Heroku

Your app was successfully deployed.
